Introduction

Introduction

This is the guide for the training programme especially developed for the training of the PhD students of the JM Burgerscentrum, Dutch research school on fluid mechanics. The guide describes the general idea of the PhD programme and presents a framework in which individual training schedules can be developed. It gives a description of the courses in the year 2010-2011, with information about the conditions to participate and instructions for registration. As mentioned, the courses are in particular meant for PhD students of the JMBC. However, also PhD students from other research schools and post-docs can participate. Moreover, persons from industries and technological institutes can also attend the courses. Additional information about the courses will be announced in the JMBC Newsletter, which appears three times per year. Information about courses and more general information about the JM Burgerscentrum can also be found on our website www.jmburgerscentrum.nl

Prof.dr.ir. G Ooms
Scientific director

Structure of the PhD programme

Structure of the PhD programme

Purpose of the PhD programme

The purpose of the PhD programme of the JM Burgerscentrum is the development of PhD students into independent researchers in the field of fluid mechanics. To reach this goal a thorough and fundamental knowledge of fluid-mechanics and their mathematical and numerical modelling is required, as well as the ability to further develop this knowledge and to apply it to solve scientific and technical problems. An important part of the PhD programme consists of the execution of a scientific research project under the supervision of an expert of the JMBC. That part is not discussed in this guide. A smaller part, of the order of half a year, consists of the participation in courses. The details of that part of the programme (the training programme) are given in this guide.

Structure of the training programme

The training programme gives a framework, in which individual training schemes can be developed. It contains the following three components:

- ♦ MSc degree courses
- ♦ PhD degree courses
- ♦ Workshops, summer schools, seminars.

The different components are meant for broadening or deepening of knowledge, and also for specialisation in certain areas of fluid mechanics. Individual training programmes are composed from elements of the three components. In the next paragraphs the three components are discussed.

MSc degree courses

The MSc degree courses are meant for PhD students (or other interested persons), who have no earlier formal training in fluid mechanics. The courses will bring those PhD students to the same level of knowledge in fluid mechanics as PhD students who did receive their MSc degree in fluid mechanics. The courses are usually selected from the advanced courses of the study programme for the MSc degree. An overview of the most relevant MSc degree courses are given in this guide ordered according to the main research themes of the JMBC. Information about time and place of these courses can be obtained from the contact persons mentioned in the course descriptions given in this guide, or can be found in the study guides of the different universities participating in the JMBC.

The number of ECTS points for the MSc degree courses to be included in an individual training programme depends on the MSc study programme of the individual. Usually it is about 9 to 15 ECTS points (each ECTS point is approximately 27 hours of study for the PhD student).

JMBC PhD courses

For a PhD student it is essential to deepen his knowledge in fluid mechanics to a level significantly higher than that of a person with a MSc degree in fluid mechanics. The PhD degree courses of the JM Burgerscentrum fulfil this purpose. The deepening of knowledge is not restricted to the area of fluid mechanics, to which the research project of a PhD student belongs. The idea of the PhD degree courses is to continue the formal training of the PhD student in a number of areas in the field of fluid mechanics, but on a post-graduate level. After his PhD degree the PhD student must be able to quickly acquaint him (her) self with a new area of fluid mechanics and solve problems in that area. As a consequence each PhD student must at least participate in three PhD degree courses. In consultation with the supervisor a PhD student can decide to follow more courses. The number of ECTS points connected to the PhD degree courses must at least be 9. The content of the courses is composed in such a way, that the courses can be followed by all PhD students (independent of their knowledge from their MSc degree programme).

The different PhD degree courses of the JM Burgerscentrum are usually given once every two years, dependent on the number of participants. The courses are concentrated in time, usually during one week. The courses are given by the senior staff members of the JMBC, but also by (internationally well-known) guest lecturers. They determine the number of ECTS points for their course. The courses can contain several elements: theoretical training, own work, demonstrations, etc. An active role of the participants is stimulated.

Workshops, summer schools, seminars or courses of other organisations

Besides MSc degree courses and PhD degree courses there is also a less-structural part of the training programme of the JM Burgerscentrum, consisting of workshops, summer schools and seminars. They can be very valuable for the education of the PhD student, and will usually be in the area of fluid mechanics to which the research project of the PhD student belongs. It is, in particular, recommended that a PhD student participate in summer schools. The JM Burgerscentrum organises regularly a summer school in a different area of fluid mechanics. Another component can be courses, not organised by the JM Burgerscentrum but by another organisation (courses from the Von Karman institute, ERCOFTAC, EUROMECH, etc.). The number of ECTS points of this part of the training programme will on average be 9.

Individual training programme

The total training load per PhD student is approximately 30 ECTS points. Deviations are of course possible; a minimum of 22.5 ECTS points is necessary, there is a maximum of 37.5 ECTS points. Taking these rules into account an individual training programme can be scheduled by a PhD student in consultation with his(her) supervisor. The programme gives a listing of the components and their timing. It is recommended to set-up the programme during the appointment of the PhD student. The supervisor decides, whether exams about the followed courses are necessary. (Each PhD course counts for 3 ECTS points)

An example of a training programme (for a PhD student without a fluid-mechanics background) is as follows:

1 st year	MSc degree courses	12 ECTS points
	PhD degree courses	6 ECTS points
	Workshop, etc.	1.5 ECTS points
2 nd year	PhD degree courses	3 ECTS points
	Workshop, etc.	1.5 ECTS points
3 rd year	Workshop, etc.	3 ECTS points
4 th year	Workshop, etc.	3 ECTS points

An example of a training programme (for a PhD student with a fluid-mechanics background) is as follows:

1 st year	PhD-degree courses	9 ECTS points
	Workshop, etc.	1.5 ECTS points
2 nd year	PhD-degree courses	9 ECTS points
	Workshop, etc.	1.5 ECTS points
3 rd year	Workshop, etc.	3 ECTS points
4 th year	Workshop, etc.	3 ECTS points

Career orientation

It is important that PhD students prepare themselves well for their future job after finishing their PhD project. Therefore each PhD student selects in consultation with his/her supervisor a course dedicated to 'career orientation' and follows this course during the third or fourth year of his/her project. Such courses are given by universities and by FOM. Via the websites of universities and FOM more details about the courses can be found. As examples some web addresses are given below:

Registration for JMBC PhD courses

Registration for JMBC PhD courses

Conditions

The PhD degree courses organised by the JM Burgerscentrum are in the first place meant for the PhD students of the JM Burgerscentrum. They have priority with respect to registration for these courses. However, as mentioned, also PhD students from other research schools, post-doc's and staff members from industries and technological institutes can participate.

Fees

- ◆ Officially registered PhD students of the JM Burgerscentrum
150,- Euro per course. Incl. course material, lunches, diner, travel expenses, and (if necessary) hotel accommodation.
- ◆ Other PhD students, scientific staff, post doc's, post-graduate students from universities
150,- Euro per course. Incl. course material, lunches and 1 general diner.
Travel expenses and hotel accommodation are not included.
- ◆ Staff members from industries, technological institutes, or other interested persons
1.000,- Euro per course. Incl. course material, lunches and 1 general diner.
Travel expenses and hotel accommodation are not included.

Registration

Registration is possible by filling in the hard copy registration form (given in this guide) and sending it to the JMBC secretariat or by online registration on www.jmburgerscentrum.org (Registration). The registration form is only necessary for the JMBC PhD courses. For OSPT, ERCOFTAC, PIV and Von Karman Courses, information about the contents and how to register can be obtained directly with these organisations.

Certificate

At request a participant in a JMBC course can receive from the JMBC secretariat a certificate concerning his/her participation.

Course evaluation form

Each participant of a JMBC course will receive from the JMBC secretariat a hard copy of the course evaluation form with the request to fill it in as soon as possible and to send it back to the JMBC secretariat. There is also the possibility to fill in the form via the website of the JMBC www.jmburgerscentrum.org (Registration). The evaluation form is anonymous. The JMBC scientific director will discuss the evaluation results with the course leader.

Course Programme 2010 - 2011

JMBC PhD courses

Registration via the JMBC Secretariat (see enclosed registration form) or online via

www.jmburgerscentrum.org (Registration)

Registration preferably one month before the start of the course

Overview of the courses for the academic year 2010-2011

♦ 28 September - 1 October 2010	Combustion
♦ 11 - 15 October 2010	Particle Technology
♦ November 2010	Cardiovascular in-vitro and ex-vitro experimental techniques
♦ 17 - 21 January 2011	CFD 2
♦ February 2011	Free surface flows
♦ March 2011	Fluid structure interactions
♦ April 2011	Turbulence
♦ May 2011	Capillarity and wetting
♦ 26 - 30 October 2011	PIV Delft
♦ November 2011	Compressible flows
♦ November 2011	Upscaling techniques and homogenization

28 September - 1 October 2010

Combustion

Prof.dr. LPH de Goey, Prof.dr. DJEM Roekaerts

Place : TUE or TUD

The objective of this 4-day course is to bring the participants to the forefront of modern computational and experimental methods for premixed and non-premixed gaseous combustion processes by giving insight into the underlying physical/chemical principles and mathematical descriptions. Starting from the governing equations for chemically reacting flows, state-of-the-art models will be derived for laminar and turbulent flames, by means of which their physical and chemical behaviour will be analysed. Computational issues for modelling these systems numerically will be discussed as well. A further focus is on the use of laser-diagnostic methods, such as LIF, Raman, CARS, and PIV, to measure local species concentrations, temperatures and flow velocities in high-temperature, chemically reacting flow systems. Practical applications will be studied for a number of examples, such as gas turbines and furnaces. The theory is tested and illustrated with simple experimental exercises in the laboratory and with numerical exercises using a code for modelling simple 1D-flame structures. The course is intended for graduate scientists and engineers, equipped with a firm basic knowledge in fluid mechanics, heat transport and combustion science, who have started to specialise in the field of combustion.

11 - 15 October 2010

Particle technology

Prof.dr. S Luding (UT), Ruud van Ommen (TUD), Hans Kuipers (TU/e) / JMBC+OSPT Course

Place : UT, Drienerburgh Hotel

Short Description

Particles can be found as granular materials in our kitchen (coffee/starch/sugar), in chemical and pharmaceutical industry (tablets/medicine/powders) in nature (sand/soil), or as solids with microstructure (ceramics/composites/metal-alloys). They are everywhere in nature and constitute over 75% of all raw material feedstock to industry – providing many challenges for innovation and fundamental science. The discrete, particulate nature of these materials leads to usually unwanted and sometimes fatal phenomena.

Particle technology is the branch of science and engineering that deals with the production, handling, modification, and use of a various particulate materials (wet or dry) in sizes ranging from nanometers to centimeters; its scope and applications span a range of industries including chemical, mechanical, petrochemical, agricultural, food, pharmaceuticals, mineral processing, advanced materials, energy, and the environment.

The purpose of this course is to give a broad overview of most fields and applications of particle technology. Due to the broad range of particle technology, only few issues can be discussed in depth and addressed by exercises. During the course, reference will be made to various more specialized courses that are given in the near future.

Participants can be PhD students in the fields of fluid-mechanics and –physics, process-technology, chemical and mechanical engineering as well as geo-sciences, informatics or mathematics. However, also other researchers who want to gain a broader overview and industrial researchers and technicians will find this course interesting.

A Poster-Viewing will be arranged on Wednesday (13.10.) in the lunch-break, so all participants are invited to bring posters of their work.

17 - 21 January 2011

CFD 2

Prof.dr.ir. C Vuik (TUD)

Location: TU Delft

<http://ta.twi.tudelft.nl/users/vuik/burgers/burg.html>

Teachers: Dr.ir. F.J. Vermolen, Prof.dr.ir. C. Vuik

Subjects: Finite element methods for the incompressible Navier-Stokes equations and iterative solution methods.

1. Finite element methods for the incompressible Navier-Stokes equations

A short introduction to the finite element method is given. The following fluid flow applications are used: Poisson equation, convection-diffusion equation and the incompressible Navier-Stokes equations. Subjects studied in more detail are: (streamline) upwind methods, problems originating from the incompressibility condition, and the linearisation of convective terms in the Navier-Stokes equations. Some remarks are given on time-dependent problems.

2. Iterative solution methods.

The solution of systems of linear equations. The main part of the course is devoted to modern iterative methods. Furthermore the following related topics are considered: direct and iterative methods for (sparse) linear systems, iterative methods to compute eigenvalues of matrices, implementation of these methods on vector- and parallel computers. As applications systems are used which originate from fluid flow problems. To illustrate the theory, practical work is done in the afternoons using MATLAB and the finite element package SEPRAN.

Preliminaries: A basic course in numerical analysis, partial differential equations and linear algebra.

May 2011

Capillarity driven flows in microfluidics

Prof.dr. F Mugele, prof.dr.ir. AA Darhuber, dr. J Snoeijs, prof.dr.ir. MT Kreutzer

University of Twente

Wetting and interfacial tensions play a crucial role for the behavior of fluids on length scales below the capillary length, which is typically of order 1mm. Typical application areas include well-established traditional fields such as coating technology and emulsification as well as recent fields such as microfluidic systems, inkjet printing technology, and immersion lithography. The course will cover the basic theoretical models used to describe thin film flows in coating, wetting, and dewetting flows. This course will address the long-standing problem of contact line dynamics, strategies of controlling liquids by patterning the wettability of solid surfaces such as passive geometric and chemical surface patterns and superhydrophobicity. Another bloc of lectures will be devoted to active surface-stress driven flows, including Marangoni flows, thermocapillarity, and electrowetting. Furthermore, we discuss two-phase flows in microchannels, including the characterization of flow patterns, the generation of bubbles and droplets will be discussed.

F Mugele | 053 489 3094 | f.mugele@utwente.nl

26 - 30 October 2011

PIV Delft

Dr.ir. C Poelma and prof.dr.ir. J Westerweel

Particle Image Velocimetry has rapidly become the standard method for measuring fluid velocities in both fundamental and applied research. In October 2009, a one-week course dedicated entirely to PIV was taught at the Delft University of Technology. We plan to teach this course again in the fall of 2011. During the course, the fundamentals of the technique will be taught, including applications in particular fields: microfluidics, turbulence, multiphase flows and aerodynamics. Next to lectures, there will be a number of practical sessions where the participants can practice their skills and see some state-of-art facilities (e.g. tomographic PIV, high-speed PIV). The course is primarily targeted at PhD students from the JMBC, who will get priority when registering: due to limitations on the available space in the practical sessions, the maximum number of participants is 35. Others interested (postdocs, faculty, researchers from institutes and industry) are welcome to apply as well, but priority is given to JMBC PhD students. Apart from a basic understanding of fluid mechanics, there is no

prerequisite knowledge. Topics: components (tracers, lasers, optics, cameras), fundamentals (cross-correlation, image density, pair loss), stereoscopic PIV, multiphase flows, laser-induced fluorescence, microfluidics, high-speed systems, volumetric methods (3D-PTV, tomographic PIV, holographic PIV), advanced processing methods (multigrid methods, deforming windows, correlation averaging), post-processing (validation, estimation of vorticity, detecting coherent structures), design & optimization of PIV systems, practical sessions. NB: this course does not replace the yearly course at DLR (Göttingen). Up-to-date info, www.ahd.tudelft.nl/piv

November 2011

Upscaling techniques and homogenization

Dr. IS Pop and dr. A Muntean

The course will present some basic mathematical techniques for the upscaling of models in complex domains, or involving highly oscillatory characteristics. Such problems appear as mathematical models for many real-world applications. Typical examples in this sense are the flow, diffusion, reaction and adsorption in porous media (e.g. in the sub-surface). This lecture provides appropriate techniques for a rational derivation of macro-scale models (effective coefficients and equations) starting from the micro scale. A particular emphasis will be on asymptotic and numerical homogenization. In the first instance, these techniques will be applied to relevant mathematical models describing diffusion in layered and perforated media; diffusion, convection, reaction and adsorption in media with a complex microstructure; fluid flow through porous media (Darcy law). Next, more complex situations as encountered in micromechanics (elastic composite materials), concrete corrosion, or enhanced oil recovery will be considered. The course is addressed to PhD students and postdoctoral researchers working on fluid-mechanics, chemical and mechanical engineering as well as geo-sciences, informatics or mathematics. It requires the standard mathematical background (calculus, differential equations) as taught at undergraduate/MSc. level. We strongly encourage the participants to bring (multi scale) problems of their particular interest to the attention of all participants. To this aim, poster sessions will be organized.

Recommended reading: Homogenization and porous media. Edited by Ulrich Hornung.

JMBC PhD courses in cooperation with other organisations

For further information and registration contact the organizer
of the below mentioned courses

Because the PIV course and the OSPT course are rather expensive and because many PhD-students want to participate in them, the JMBC cannot reimburse the complete costs for these courses. For JMBC PhD-students the JMBC contributes 500 Euro for the fee and reimburse the travel and hotelcosts. (The remaining costs have to be paid by the group to which the PhD-student belongs. The JMBC will not charge the usual 150 Euro). Other PhD-students and staff members from industries and institutes pay the fees mentioned by the organising secretariats of the PIV- and OSPT course. (The JMBC will not charge the usual 150 or 250 Euro).

March 2011

PIV DLR Goettingen, Germany

MSc degree courses

General fluid mechanics

Advanced fluid mechanics I (357001)

Dr. D van der Meer, UT

The objective of this course is to acquire a firm base in classical fluid mechanics. The emphasis is on analytical solutions and their physical implications. Advanced Fluid Mechanics will serve as an introduction to the basic equations and phenomena needed in CFD, turbulence, acoustics and granular flows. Subjects: Conservation laws, vorticity, potential flow in 2D and 3D, conformal mapping and 2D flow, Zhukovsky airfoils, waves, shallow water equations, flow at low Reynolds number, Stokes and Oseen solutions, Hele-Shaw flow, flow at high Reynolds number, boundary layers, self-similarity, hydrodynamic stability, compressible flow, Laval nozzle, shock waves.

Fore more information contact

D van der Meer | 053 489 2387 | d.vandermeer@utwente.nl

Compressible flows

Gasdynamics I (AE4-140)

Prof.dr.ir. PG Bakker, TUD

1. Introduction: notations, definitions, equations of state, entropy, speed of sound, integral- and differential form of governing equations, Euler equations, entropy equation, 'weak' solutions, entropy condition I, moving shocks, (x,t)- diagram, entropy conditions II, III, numerical treatment.
2. One-dimensional unsteady flow, linear: acoustic waves, d'Alembert's solution, characteristic method, discontinuities, Piston problem, simple waves, Riemann's initial value problem.
3. One-dimensional unsteady flow, non-linear: characteristic equations, Riemann invariants, simple waves, Riemann's initial value problem, Hugoniot- and Poisson curves, iterative solution of Riemann problem, characteristic method, compression wave, wave interaction, analogy with 2D-steady.
4. Burgers equation for simple waves: non-viscous Burgers equation, shock equation, shock formation, entropy conditions, viscous Burgers equation, wave interactions.
5. Traffic waves: definitions, concepts traffic equation, characteristics and discontinuities, traffic light, chain collision

For more information contact

PG Bakker | 015 278 5907 | P.G. Bakker@tudelft.nl

Gasdynamics II (AE4-141)

Prof.dr.ir. PG Bakker, TUD

1. Two-dimensional unsteady flows: flow equations vector form of flow equations, diagonalisation, left- and right eigenvectors, 2D wave propagation, enveloping of waves.
2. Non-viscous steady 2D flow: diagonalisation, characteristic directions, hyperbolicity, 'time-like' and 'space-like', flow aligned co-ordinates, compatibility, characteristic methods, Prandtl-Meyer expansion, nozzle design, transonic nozzle flow.
3. Burgers equation for 2D simple waves: non-viscous Burgers equation, shock formation, biconvex airfoil, asymptotic behaviour of shocks, wave interaction.
4. Qualitative theory of 1D viscous flows, equations governing quasi 1D viscous flows, qualitative theory of 2nd order dynamical systems, qualitative aspects of the solutions of the quasi 1D flow equations, frictional effects, Fanno equation, internal structure of a shock wave.

For more information contact

PG Bakker | 015 278 5907 | P.G. Bakker@tudelft.nl

Aeroacoustics (115440)

Dr. SJ Rienstra, TUE

Aeroacoustics is the study of sound production by unsteady flows of gas and liquids. After an introduction of basic acoustical concepts and a short discussion of wave propagation in pipes and resonators the course focuses on Lighthill's theory of sound production by flows. Vortex sound theory will be introduced on the basis of an energy balance. The theory is illustrated by simple applications to the clarinet, thermoacoustic instability, acoustical behaviour of air bubbles in water, whistling phenomena.....etc.

For more information contact

SJ Rienstra | 040 247 4603 | s.w.rienstra@tue.nl

Multiphase flow, dispersed media and rheology

Multiphase flow and heat transfer (AP3181D)

Dr.Eng. LM Portela, TUD

The course on multiphase flow covers basic parameters for design and operation of process equipment, interfacial phenomena, waves in two-phase flow, dimensionless numbers for scale-up, flow regime dependent modelling, two-phase pressure gradients and phase hold-ups for separated, slug and bubble gas/liquid pipe flow and flow regime maps for inclined tube flows. It will furthermore provide introductions to dispersed gas/liquid flows in simple and complex geometries and dispersed flows with solid particles. Moreover, it will address the two-phase heat transfer aspects of boiling liquids. The course is concluded with a brief introduction to the course on Computational Multiphase Flows.

For more information contact

LM Portela | 015 278 2842 | l.portela@tudelft.nl

Continuümmechanics

Dr. D van den Ende, UT

The continuum model, kinematics, conservatoin laws, the stress tensor, simple materials, special constitutive eqauntions, special types of flow, rheological material functions. This course will not be lectured on specific dates, but on an individual base in the form of self-study, after making an appointment with Dr. D van den Ende.

For more information contact

D van den Ende | 053 489 3105 | h.t.m.vandenende@utwente.nl

Capillarity and Wetting Phenomena

Prof.dr. F Mugele, UT

Capillarity is the study of the interfaces between two immiscible fluids or a fluid and a solid.

Topics of this course are surface tension, capillary rise, thin films, wetting and dewetting, electrowetting, capillary waves, surfactants, special interfaces.

Previous knowledge: Physics of Fluids or another introductory course in fluid mechanics (required). Course material: Pierre-Gilles de Gennes, Françoise Brochard-Wyart, David Quéré, Capillarity and Wetting Phenomena, Springer Science and Business Media, New York USA (2003). Examination: exercises during the course, written/oral exam at the end of the course.

The course will be given between september and end of november.

Elementary two-phase flow with heat transfer (4P540)

Dr. CWM van der Geld, TUE

This is an introductory course in two-phase flow. Averaging procedures and correlations to be used in practise to compute f.e. pressure drop and heat transfer with boiling. Distribution parameter to extend simple one-dimensional approximate computations. Forces on particles and bubbles, and trajectory computations. Lagally theorem, lift forces and variational approaches. Basic thermodynamics using the grand canonical to introduce interfaces and surface tension. Excess free energy and demonstration that boiling occurs on nucleation sites or at boundaries first. Classic two-component mass diffusion theory: Stefan, filmmodel of the air layer with condensation. Interaction of heat and mass transfer in the rapid evaporation of drops. Mollier diagram. Dropwise condensation.

Nanoparticulate Materials

Prof.dr. A Schmidt-Ott

- What is special about nanoparticulate and nanophase materials? Basic properties (electrical, optical, magnetic, mechanical, chemical) and size effects
- Synthesis of nanoparticulate and nanophase materials, e.g.in flow reactors
- Characterization of nanoparticulate and nanophase materials, including on-line characterization of particles in gas suspension
- present and future applications of nano-composites including solar cells, fuel cells, hydrogen storage, catalysis, magnetic, optical, structural materials

Computational Multiphase Flow (AP3551)

Dr.Eng. LM Portela, TUD

This course consists of 12 weeks, starting in the beginning of September, in which the behaviour and description of flows, whereby one phase is dispersed in another phase, will be discussed. The Euler-Lagrange and Euler- \tilde{A} Euler approaches to dispersed multiphase flows will be discussed. During the course, the students will develop a small CFD code, to which subsequently the various important aspects of dispersed flows will be added. The influence of different interaction forces (drag, lift, added mass, etc.) between the phases and the effects of turbulence will be studied using the CFD \tilde{A} code.

Transport phenomena in conversion processes and manufacturing (st474)

Prof.dr.ir. HEA van den Akker, TUD

Various aspects of manufacturing and conversion processes will be discussed in the course. The topics are: viscous flows in quasis 1D thin layers, extruders, jets and sprays, entrainment, particle motions, two-phase flow, turbulence, stirred vessels, heat and mass transfer. Applications are found in industrial processes and product manufacturing.

Multiphase Reactor Engineering (CH3062)

Dr.ir. JR van Ommen, TUD

This is an elective course for MSc en PhD students, taught in the first quarter of the academic year. The course treats the various types of multiphase reactors, such as packed beds, fluidized beds, and bubble columns. A large part of the course consists of modelling assignments, to be made in teams of two or three persons (3 ECTS).

Nanofluidics

Prof.dr.ir. F Mugele, dr. J Eijkel, dr. S Kooi, UT

Introduction: fundamental aspects, intrinsic length scales & geometry applications.

Solid-liquid interfaces: interactions, specific adsorption/desorption, electrolytes near interfaces

Hydrodynamics at small scales: laminar flow; slip vs. no-slip; mixing at small scales

Three-phase systems: capillary forces, (control of) wetting, superhydrophobicity

Electrokinetic effects: electroosmotic pumping, electroviscous effect

Electrophoresis and separation techniques

Colloids (I): chemistry, stability, interactions

Colloids (II): physical properties, self-assembly

Study material: review articles and course script.

Evaluation: assignments during course; final oral presentation about a specific subject

Physics of Bubbles (357201)

Dr. M Versluis, UT

The Bubbles course consists of 2 parts: 4 lectures on the physics of single bubbles and 2 lectures on the behavior of multiple bubbles and bubble clouds. The course treats the forces on bubbles, the acoustics of bubbles and bubble clouds, microstreaming and jets due to bubble oscillation, cavitation and collapse. Subjects: Bubble formation and stability. Static diffusion. Blake threshold. Bubble dynamics. The mass-spring analogy. Damping mechanisms on bubbles. Forced oscillations. Pressure emitted by an oscillating bubble. Forces on bubbles. Equation of motion. Trapping and manipulation of bubbles. Contrast agent microbubbles. Diagnostic and therapeutic applications. Experimental techniques. Acoustical and optical characterization. Non-linear behavior. Harmonics. Surface modes. Cavitation. Sonoluminescence. Shockwaves. Microstreaming. Recommended book: Cavitation and bubble dynamics by Christopher Earls Brennen.

M Versluis | 053 489 6824 | m.versluis@utwente.nl

Granular Matter (358003)

Dr. JH Snoeijer, UT

Granular matter can be considered as the fourth state of matter: Depending on the situation, granular matter can behave as a solid, a liquid, or a gas, but always has its own peculiar properties. When dry sand is poured, it acts as a fluid. The pile on which it is poured is solid-like, stabilized by forces in between the sand beads. When dry sand is strongly shaken or fluidized through a gas stream, it behaves gas-like. This course gives an introduction to granular matter in its various forms.

Advanced Numerical Methods (WI4212) 6 ECTS

Prof.dr.ir. C Vuik and dr. J Ryan TUD

This course is an introduction to hyperbolic partial differential equations and a powerful class of numerical methods for approximating their solution, including both linear problems and nonlinear conservation laws. These equations describe a wide range of wave propagation and transport phenomena arising in nearly every scientific and engineering discipline. Several applications are described in a self-contained manner, along with much of the mathematical theory of hyperbolic problems. High-resolution versions of Godunov's method are developed, in which Riemann problems are solved to determine the local wave structure and limiters are then applied to eliminate numerical oscillations. These methods were originally designed to capture shock waves accurately, but are also useful tools for studying linear wave-propagation problems, particularly in heterogeneous material.

CFD 1 - Incompressible flows (AE4-151)

Dr.ir. MI Gerritsma, TUD

Subjects treated: Introduction to Computational Fluid Dynamics. Classification of partial differential equations and well-posedness. Finite volume methods, finite difference methods, finite element methods, boundary element methods and spectral element methods. For the incompressible Navier-Stokes equations two topics will be treated in depth: the relation between the (hyperbolic) convective terms and the (elliptic/parabolic) diffusive terms, and the role of the pressure in incompressible flows and the ensuing compatibility conditions between velocity and pressure approximation. Examination takes place in the form of an assignment in which the student writes and analyzes an incompressible Navier-Stokes solver. This assignment will be concluded with an oral examination.

H Bijl | 015 278 5373 | h.bijl@tudelft.nl

Application of the Finite Element Method to heat and flow problems

Dr.ir. CCM Rindt, TUE

In this course the general method to construct a numerical solution of a second order partial differential equation with the Finite Element Method (FEM) is elucidated. Practical aspects like automation, quadrature rules and accuracy of the numerical solution are also highlighted. More specifically, the FEM-method is applied to the solution of incompressible flows (Navier-Stokes equations) and thermally driven flows (Boussinesq approach). Besides, several solution methods of the Navier-Stokes equations are presented like the penalty function approach and projection schemes. Finally, some numerical aspects are shown for time-dependent problems. Beside the oral courses, there is also the possibility to practice on some classical fluid dynamic problems like the flow over a backward facing step and the flow around a cylinder.

For more information contact

CCM Rindt | 040 247 2978 | c.c.m.rindt@tue.nl

Modelling of Physical Phenomena (4P560)

Dr.ir. JGM Kuerten, TUE

The subject is the modelling of physical phenomena, i.e. the steps necessary to translate a physical problem into a mathematical model and its solution. For many problems in fluid dynamics the mathematical model is a partial differential equation. In the lecture series a number of problems from thermal and fluid mechanics will be studied in this way. Moreover, attention will be paid to analytical and numerical solution methods. Examples which will be treated are: waves in shallow water, heat flow in a bar and air flow around the wing of an airplane.

Advanced Programming in Engineering (1158500 - 5.0 EC)

Prof.dr. S Luding, UT

2nd-3rd quarter 2010-11 . Goal of the lecture is to teach the students the basics of various algorithms and methods used everyday in mechanical engineering, civil engineering, and physics. This will go deep into the basics, involving Advanced Computational Programming and Algorithms. The goal is not using commercial software packages or functions from, for example, Matlab, but to understand the Methods “from the inside”. There will be classroom-lectures to teach basics and theory as well as practical exercises where the learned knowledge will be implemented on the computer. Several examples will be treated (we would like to receive ideas of examples which relate this lecture to other courses where there is not time to go that deep into the programming) which build upon other lectures (fill in examples or specific courses here). Unique about this lecture is that some of these examples will be treated by different methods in parallel (for example diffusion can be dealt with by finite differences, finite elements, or stochastic methods). Dependent on the number of participants, this will be either done by split groups, or sequentially so that the students get familiar with the strengths and weaknesses of various numerical methods and approaches. Required: Basic Programming Skills (!) and solid Math, Physics, Engineering, Informatics background.

Theory of chaos and dynamical systems

Applied Analytical Methods (150950)

Prof.dr. EWC van Groesen, UT

The goals of the course are 1. to learn to recognise variational structures of various kinds in many problems from the physical and technical sciences, and 2. to learn the mathematical methodology and techniques to exploit these structures (in equations and solutions) for a detailed investigation. Students learn how many problems are described by some variational principle (the principle of minimal potential energy, the action principle for dynamical systems), and that dissipative or conservative properties can be recognised by investigating specific functionals. Special solutions, the physical ‘coherent structures’ such as solitary waves (solitons) in fluid dynamics or electromagnetism, can then be characterized and obtained in a variational way. The mathematical methods include the calculus of variations, classical mechanics, dynamical system theory and eigenvalue problems. These methods are introduced and extended to infinite dimensional systems (described by partial differential equations). Most applications will be from fluid dynamics (surface waves) and optics.

Topics:

1. Unconstrained variational problems: Theory of first and second variation, natural boundary conditions; variational structures in nature and dynamics: principle of minimal energy, Lagrangian and Hamiltonian systems.
2. Constrained variational problems: Lagrange’s multiplier rule; Linear Eigenvalue. Problems: Rayleigh quotient, comparison theorems.
3. Variational restrictions: Approximations in solutions or model equations by restriction of the functional to suitable subsets. Introduction to numerical methods like FEM and variational consistent modelling.

Appendices: A. Fluid Dynamics | B. Optics | C. Solitons and wave groups

Chaos (3T220)

Prof.dr.ir. W van de Water, TUE

Chaos is the disordered behavior of nonlinear systems with just a few degrees of freedom: very simple but nonlinear systems. We will see why the route to chaos is often universal.

This universality can be expressed in terms of a renormalisation theory, which expresses the invariance of the dynamics under a change of scale. We will discuss the Feigenbaum--Cvitanovic renormalisation equation for the route to chaos through period doublings. Next, we will walk the road to chaos along the golden mean in the case of competition of nonlinear oscillators. The emphasis will be on systems with dissipation, but we will see a simple geometric description of the route to chaos in Hamiltonian systems. A theory of scales is beautifully illustrated by the concept of fractals. It is possible to give a thermodynamic description of these strange things. We will discuss practical applications to control nonlinear systems and to influence chaos. The course offers fundamental insight in this modern subject, but the emphasis is on practical application in simple systems. Interactive computer simulations of real systems offer a vivid illustration of the more theoretical material. The course also offers a unique exposure to modern literature on chaos: During one half of the course the basic concepts are introduced, and in the other half each participant presents an article on chaos which appeared in the past year in Physical Review Letters. Of course, adequate coaching is offered.

Combustion

Chemistry and transport in energy conversion processes (4S580)

Prof.dr. LPH de Goey, TUE

More than 80% of our energy is generated by combustion of fossil and future (bio)-fuels in equipment like engines, gas turbines, furnaces in the (process)-industry and burners in domestic and industrial appliances. The physical and chemical processes, which describe the combustion phenomena in the different mentioned appliances, will be treated. After a global description of the different combustion methods and their application, the global balances and the elementary processes in reacting flows will be presented. Ideal reactors, like the perfectly stirred reactor and the homogeneous reactor, form the starting point of the treatment of ignition phenomena. Flames and flame fronts will be discussed afterwards. The movement of premixed flame fronts on Bunsen burners, surface burners and in Otto engines will be analyzed. Non-premixed flame fronts, like on burners, furnaces and Diesel-engines, will be treated afterwards and the course will be finished with an analysis of the influence of combustion processes on the environment. Software for the analysis of simple combustion processes, like perfectly stirred reactors, plug-flow reactors and flat flame fronts will be used in the guided self-study.

Gasturbines (4P700)

Dr.ir. HC de Lange, TUE

The gasturbine is one of the most often used machines in the production of mechanical power. In this course a number of application areas (aero engines, turbochargers, industrial applications) will be discussed. Using the book by Cohen et al. the thermo- and fluid dynamics of turbomachines is studied. First, different systems (using intercooling, regeneration, etc.) are compared using simple thermodynamical theory. They show the applicability and efficiency of different processes. Second, the working principles of both radial and axial compressors are explained based on compressible flow equations (both one- and more dimensional). Using aerodynamical arguments the working of a combined compressor/turbine is discussed, both in the design-point as well as at offdesign conditions. Besides the stationary flow considerations, a number of dynamical aspects (acceleration, stall, surge, etc.) will be discussed.

Books: H.I.H. Saravanamuttoo, G.F.C. Rogers and H. Cohen, 'Gasturbine theory', 2001.

HC de Lange | 040 247 2129 | h.c.d.lange@tue.nl

Turbulent reacting flows (AP3561)

Prof.dr. DJEM Roekaerts, TUD

Course Material: Thierry Poinsot and Denis Veynante “Theoretical and numerical combustion”, Edwards, 2005, ISBN: 1-930217-10-2. This text describes basic techniques and recent progress in the field of numerical combustion. Lecture notes or articles on additional topics. Models for interaction between turbulent flow and chemical reaction are treated. The main question addressed is by which method or model the mean properties of the flow can be obtained without having to solve the transport equations in full detail. Such methods are useful in the design of industrial combustion chambers, chemical reactors and in the description of reactions in the atmosphere. In the first part, basic aspects are developed (transport equations, reaction kinetics, non-dimensional numbers and regime diagrams, fundamentals of a statistical description, laminar flames). In the second part a more extensive introduction to turbulent combustion is presented. Methods for handling the closure problems arising in averaged or filtered transport equations are described and evaluated (RANS, LES, flamelet model, probability density function method). Simple application exercises are made. Depending on the specific interest of the student, additional topics can be added.

Advanced combustion diagnostics using laser techniques (4P620)

Dr. NJ Dam, TUE

The main goal of this course is to achieve knowledge and understanding of the use and applications of various laser-optical techniques for diagnostics of high temperature systems in general, and various combustion systems in detail. Of specific interest is to develop insight into different non-intrusive techniques for species concentration measurements, temperature measurements and methods for particle characterization in high temperature environments. After a brief overview of laser-optical diagnostics techniques and an introduction to basic molecular spectroscopy and optical-laser instrumentation, the course involves the following subjects:

- Diagnostics of soot characterization by scattering/extinction and Laser-Induced Incandescence (LII);
- Theory and fundamentals of Laser-Induced Fluorescence followed by thermometry and imaging applications;
- Rayleigh and Raman scattering for species concentration measurements and thermometry;
- Non-linear optical techniques, e.g. Four-Wave Mixing techniques and Polarization spectroscopy for minor species detection;
- Finally an overview of emerging techniques, e.g. Ballistic imaging for diagnostics in dense sprays and picosecond LIDAR measurements for spatially resolved measurements in environments with limited optical access.

Engines: Modeling and analysis

LMT Somers, TUE

In this lecture series the student will apply the first law of thermodynamics to the general systems of reacting mixtures. Using temperature dependent thermodynamic properties (NASA polynomials) a cycle simulation model and an experimental analysis script will be derived.

Modeling: a matlab based computer program to simulate a real engine cycle using a modeled combustion progress (Wiebe-like). The oral lectures are short and only meant to give a concise introduction to the problem. A systematic approach is used to increase the complexity in a gradual way through the organization of the lectures series. Emphasis is not on numerics but on physics.

Analysis: experiments performed on the University Racing team engine testbench (600 cc Suzuki) will be analyzed. Using the same first law analysis as above, the Sankey diagram will be determined and engine parameters like thermal efficiency, BMEP etc, computed. The course is mainly in hands-on exercise and a notebook and Matlab are required. Final term: written report .

LMT Somers | 040 247 2107 | l.m.t.somers@tue.nl

Fuels and Lubes (4N850)

Dr.ir. CCM Luijten, ir. HJ van Leeuwen, dr.ir. MD Boot

Geopolitical, environmental and societal factors are forcing the automotive industry to develop more efficient and cleaner burning engines. In current engine design processes, fuels and lubricants are regarded as “facts of life”. However, future requirements in terms of fuel efficiency and emissions, may be easier to meet when the chemical structure of fuels and lubricants is adjusted in a proper way. Therefore, a lot of research is going on worldwide to characterize alternative fuels such as biofuels, synthetic fuels, oxygenated fuels, dual fuelling strategies, and so on. The same holds for lubricants research. In the course, starting from knowledge of the molecular (hydrocarbon) structure of fuels and lubricants available today (plus the likely options for the future), the student will learn to compute or estimate the relevant physical (density, saturation pressure, viscosity) and chemical properties (e.g. auto-ignition, heating value, adiabatic flame temperature). Essential engine processes such as lubrication, spray formation, evaporation, and formation of emissions (such as NO_x and soot) in an engine will be discussed with emphasis on which physical, chemical and tribological properties of fuels and lubricants play a role. The ultimate goal is the ‘reverse engineering’ step: given the requirements to the engine, the student should be able to ‘design’ the proper fuel and lubricant for a given application. Near the end of the course trends in fuels and lubricants are discussed, and further illustrated by a couple of guest lectures by leading experts.

Powertrain components (4AT00)

Dr.ir. CCM Luijten, dr.ir. LMT Somers, dr.ir. T Hofman

This introductory course on automotive power trains (including engine and transmission), covers the basic technology behind automotive vehicle propulsion. In the introductory lecture, basic road load forces will be discussed in order to derive the amount of torque and power a vehicle power train should deliver. Next, the principles of 4-stroke Internal Combustion Engine are discussed (components, kinematics and operating characteristics). Some elements of ICE operation (a.o. gas exchange, cycles, thermo chemistry and fuels, fuel consumption and emissions) are discussed in more depth in order to enable students to make quantitative computations. The course continues by treating the history and basic principles of the automotive drive train and its components. The aim of this part is to obtain a broad (and in some aspects deep) insight in components, systems and system designing of vehicle drive trains. Some basic powertrain modeling techniques will be treated, followed by the somewhat more detailed analysis of the Toyota Prius powertrain. This example and others will be used to explain the challenges that powertrain designers are facing nowadays. The course consists of 18 hours of lectures, with additional practical exercises in the laboratories of Automotive Engineering Science (2x half a day).

River Systems (540021)

Dr. F Huthoff, drs. JJ Warmink, UT

Introductory into the physical processes in natural river systems. Phenomena in natural river system are explained and described in a qualitative way. The following processes are discussed: meandering, shifting riverbeds, bank erosion, stream roughness and sort processes.

This course is a prerequisite for Shallow water flow (540041) and Transport processes and morphology (540042).

For more information contact

F Huthoff | 053 489 3911 | f.huthoff@utwente.nl

Shallow water flow (540041)

Dr.ir. JS Ribberink, UT

In this course steady and unsteady shallow water flows are discussed for rivers, with topics such as backwater curves, flood waves, tidal flows. Dynamic behavior and physical mathematical modeling will be discussed particularly for 1-D flows. Case studies from river management will be used to illustrate flow phenomena and the influence of human interventions. Application of a 1-d river model will be exercised in a computer class.

For more information contact

JS Ribberink | 053 4892767 | j.s.ribberink@utwente.nl

Transport processes and morphology (540042)

Dr.ir. JS Ribberink, UT

This course involves i) transport processes of dissolved substances and sediment (advection, diffusion, exchange with bottom), ii) morphologic processes, as occur in surface water systems. Understanding and modelling spreading of suspended sediment, bed load of sand or gravel, erosion or sedimentation of the bottom (morphology). Insight in characteristics and dynamic behaviour, particularly for river systems. The basis is formed by 1-D physical mathematical models. Transport processes and morphology, either or not affected by human interventions, will be analysed for practical examples. In a computer exercise, a 1-D (numerical) model will be applied to a particular morphologic river problem.

JS Ribberink | 053 4892767 | j.s.ribberink@utwente.nl

Marine Systems (540024)

Dr. TAGP van Dijk, UT & Deltares

Introduction to physical processes in a marine environment. The physical processes are described and explained in a qualitative way. The following processes are discussed: behaviour of waves, tide, sediment transport, beach morphology as well as the main characteristics of estuaries, river delta's, continental shelves and shallow seas. The course Marine Systems provides knowledge for Marine Dynamics II (540081) and Seminar Morphology (540082)..

TAGP van Dijk | 053 489 4705 | t.a.g.p.vandijk@utwente.nl

Marine Dynamics (540080)

Prof.dr. SJMH Hulscher, UT

The first part of this course (Marine Processes) focuses on a quantitative description of marine processes, which were considered in a more qualitatively sense in the course Marine Systems (540024). The second part of this course (Coastal & Offshore Engineering) focuses on engineering applications in marine environment, such as coastal protection, harbours, offshore wind farms, etc.

For more information contact

SJMH Hulscher | 053 489 4256 | s.j.m.h.hulscher@utwente.nl

Seminar Morphology (540082)

Prof.dr. SJMH Hulscher, UT

This course covers four topics related to morphology of rivers, estuary, coasts and seas in which physical processes play an important role. Understanding and prediction of morphological developments are important aspects of water management. Practical examples are the deepening of the Western Scheldt, maintaining the coast line, and the protection of pipe lines in a dynamic sea bed. Scientific papers will be used to study these topics. Students present and discuss these papers based on a number of questions. In addition, each student has to write a report on a specific topic and present a poster on this topic to fellow students and department members.

Micro-scale fluid mechanics

Microfluidics (WB1429)

Prof.dr.ir. J Westerweel TUD

This course is an introduction to fluid mechanics at small scales. The subjects treated are: Scaling laws, Navier-Stokes equations for micro-scale gas and liquid flows, for electroosmotic flow, electrophoresis, dielectrophoresis, dispersion and diffusion, capillary effects, experimental techniques, applications in flow control, flow sensors, valves, pumps, mixers, filters, separators, heaters and life science applications.

Experimental techniques in fluid mechanics

Experimental techniques in physics of fluids (358002)

Dr. C Sun, UT

In this course we will discuss the most common experimental techniques that are used in fluid dynamics. Specific advantages, but most of all the limitations of certain techniques will be presented. The course is comprised of lectures, informative lab tours, “hands-on” lab tours, short presentations of experts in the course field and partial assignments, based on review articles from specialist literature. The course is completed by performing an experimental assignment, and a written and oral presentation of the results
